BRE Client Report

BRE Dwelling Level Housing Stock Modelling and Database for the Royal Borough of Kingston upon Thames

Prepared for: Nick Millard, Property Inspection Team Manager
Date: 19 December 2014
Report Number: 297-048 Issue: 1
This report is made on behalf of Building Research Establishment Ltd. (BRE) and may only be distributed in its entirety, without amendment, and with attribution to BRE to the extent permitted by the terms and conditions of the contract. BRE’s liability in respect of this report and reliance thereupon shall be as per the terms and conditions of contract with the client and BRE shall have no liability to third parties to the extent permitted in law.
Executive summary

- The Royal Borough of Kingston upon Thames commissioned BRE to undertake a series of modelling exercises on their housing stock. This report describes the modelling work and provides details of the results obtained from the dwelling level model and database. The database\(^1\) is also provided to the council to enable them to obtain specific information whenever required.

- A Health Impact Assessment (HIA) was also commissioned and the results of this are provided in a separate report.

- The detailed housing stock information provided in this report will facilitate the delivery of Kingston upon Thames' housing strategy and enable a targeted intervention approach to improving housing. In addition to this there are also several relevant government policies – the Housing Act 2004, Housing Strategy Policy, Local Authority Housing Statistics (LAHS) and the Green Deal/ECO.

- The main aims of this work were to provide estimates of:
  
  - The percentage of dwellings meeting each of the key indicators\(^2\) for Kingston upon Thames overall and broken down by tenure and then mapped by COA (private sector stock only)
  
  - Information relating to LAHS reporting for the private sector stock - category 1 hazards, as well as information on EPC ratings

- BRE Housing Stock Models were used to provide such estimates at dwelling level with a focus on private sector housing. The key indicators provide Kingston upon Thames with detailed information on the likely condition of the stock and the geographical distribution of properties of interest.

- A stock modelling approach has been developed and used by BRE for many years and the most recent 2014 models have been updated to make use of the results of the 2011 English Housing Survey (EHS)\(^3\) and additionally now incorporate a technique known as geomodelling\(^4\) which makes use of Ordnance Survey (OS) data. These dwelling level models are used to estimate the likelihood

---

\(^1\) Whilst this current report focusses on ward and COA level data, the database includes information at LSOA level to enable comparison with health data provided by Kingston upon Thames for the bespoke analysis included in the HIA report.

\(^2\) Presence of a HHSRS category 1 hazard, presence of a category 1 hazard for excess cold, presence of a category 1 hazard for falls, dwellings in disrepair, fuel poverty (10% and Low Income High Cost definitions), dwelling occupied by a low income household and SimpleSAP rating.

\(^3\) 2011 is the latest available data. Prior to the 2014 models EHS 2009 data was used.

\(^4\) The OS data has been used to update a number of the model inputs – the main value of the OS data is the ability to determine the dwelling type with much greater confidence – see Appendix B for more information.
of a particular dwelling meeting the criteria for each of the key indicators. These outputs can then be mapped to provide the authority with a geographical distribution of each of the key indicators which can then be used to target resources for improving the housing stock.

- The headline results are as follows:

**Headline results for Kingston upon Thames**

1,368 dwellings in the private rented sector have category 1 Housing Health and Safety Rating System (HHSRS) hazards. This equates to 9% of properties in the private rented sector. See full results

The highest concentrations of fuel poverty and excess cold in the private sector are found in the wards of St Mark’s and Berrylands. See full results

The highest concentrations of all HHSRS hazards in the private sector are found in the wards of St Mark’s, Berrylands and Beverley. See full results

The average SimpleSAP ratings for all private sector dwellings in Kingston upon Thames is 54, which is worse than England (55). For the owner occupied stock in Kingston upon Thames the figure is 53 and for the private rented sector it is 57. See full results

Maps by COA have been provided for the above key indicators. See maps

The total cost of mitigating category 1 hazards in Kingston upon Thames’s private sector stock is estimated to be £13.9 million. See full results

9.4% (5,284) of private sector dwellings and 10.4% (1,505) of private rented dwellings in Kingston upon Thames are estimated to have an EPC rating below band E. See full results
Key illustrations of headline results

- The table below shows the results for 7 of the key indicators in Kingston upon Thames compared to England (EHS 2011) and split into all stock and private sector stock. The data shows that the private stock in Kingston upon Thames is better than the private stock for England for all hazards.

1 Introduction

The Royal Borough of Kingston upon Thames commissioned BRE to undertake a series of modelling exercises on their housing stock. This report describes the modelling work and provides details of the results obtained from the dwelling level model and database. The database is also provided to the council to enable them to obtain specific information whenever required.

A Health Impact Assessment (HIA) was also commissioned and the results of this are provided in a separate report.

The stock models and database provide the council with dwelling level information on various key housing indicators, focussing on private sector housing. The key indicators provide Kingston upon Thames with detailed information on the likely condition of the stock and the geographical distribution of properties of interest. These properties are likely to be suitable targets for energy efficiency improvements or other forms of intervention, such as mitigating Housing Health and Safety Rating System (HHSRS) hazards. The key indicators are split into indicators related to house condition, energy efficiency and household vulnerability as shown in Table 1 (see Appendix A for full definitions).

N.B. Presence of category 1 hazard for falls does NOT include the hazard of falling between levels

The single indicators shown in Table 1 can also be combined within the database to provide powerful information on the housing stock, for example dwellings suffering from excess cold and also occupied by households on a low income. The true potential of the database lies in its ability to produce combined indicators such as this, as it allows council officers to explore the stock and to assess the likely scope of any programmes they might wish to implement.

It is also possible to extract other information from the database which is of use to local authorities. This information includes estimates relating to the Department for Communities and Local Government’s...
(DCLG) Local Authority Housing Statistics (LAHS) reporting of Energy Performance Certificate (EPC) ratings and costs of mitigating hazards.

The key indicators and other information are derived from the Housing Stock Database which is made up of a series of Dwelling Level Stock Models. The BRE dwelling level stock models have been used for many years to provide key housing indicators to local authorities. The most recent 2014 models have been updated to make use of the results of the 2011 English Housing Survey (EHS)\(^5\) and additionally now incorporate a technique known as geomodelling\(^6\) which makes use of Ordnance Survey (OS) data. The models also make significant use of the Experian UK Consumer Dynamics Database of dwelling and household indicators as inputs to the models.

The information in the database can be used to ensure the council meets various policy and reporting requirements. For example, local housing authorities are required to review housing conditions in their districts in accordance with the Housing Act 2004\(^7\).

Furthermore, having this information available will also help to facilitate the delivery of Kingston upon Thames housing strategy. It will enable a targeted intervention approach to improving housing; therefore allowing the council to concentrate their resources on housing in the poorest condition or with the greatest health impact.

### 1.1 Project aims

The main aim of this project was to provide data on key private sector housing indicators for Kingston upon Thames. Furthermore, Kingston upon Thames also requested estimates for several other housing-related elements. The main aims of this work were therefore to provide estimates of:

- The percentage of dwellings meeting each of the key indicators for Kingston upon Thames overall and broken down by tenure and then mapped by COA (private sector stock only)
- Information relating to LAHS reporting for the private sector stock - category 1 hazards, plus information on EPC ratings

This report looks firstly at the policy background and why such information is important for local authorities. Secondly, it provides a brief description of the overall stock modelling approach. Finally, this report provides the modelling results for Kingston upon Thames covering each of the main aims above.

---

\(^5\) 2011 is the latest available data. Prior to the 2014 models EHS 2009 data was used.

\(^6\) The OS data has been used to update a number of the model inputs – the main value of the OS data is the ability to determine the dwelling type with much greater confidence – see Appendix B for more information.

2 Policy background

The detailed housing stock information provided in this report will facilitate the delivery of the housing strategy for Kingston upon Thames and enable a targeted intervention approach to improving housing. This strategy needs to be set in the context of relevant government policy and legislative requirements. These polices either require reporting of housing-related data by local authorities, or the use of such data to assist in meeting policy requirements. The main policies and legislative requirements are summarised in the following sub-sections.

2.1 Housing Act 2004

The Housing Act 2004\(^7\) requires local housing authorities to review housing statistics in their district. The requirements of the Act are wide-ranging and also refer to other legislation which between them covers the following:

- Dwellings that fail to meet the minimum standard for housings (i.e. dwellings with HHSRS category 1 hazards)
- Houses in Multiple Occupation (HMOs)
- Selective licensing of other houses
- Demolition and slum clearance
- The need for provision of assistance with housing renewal
- The need to assistance with adaptation of dwellings for disabled persons

2.2 Key housing strategy policy areas and legislation

In the report “Laying the Foundations: A Housing Strategy for England”\(^8\) Chapters 4 and 5 focus on the private rented sector and empty homes.

2.2.1 Private rented sector

There has been significant growth in the private rented sector in recent years and new measures are being developed to deal with rogue landlords and to encourage local authorities to make full use of enforcement powers for tackling dangerous and poorly maintained dwellings. The report encourages approaches which work closely with landlords whilst still operating a robust enforcement regime (e.g. Landlord Forums and Panels across the country).

2.2.2 Health inequalities

The government’s white paper “Choosing Health”\(^9\) states that the key to success in health inequalities will be effective local partnerships led by local government and the NHS working to a common purpose and reflecting local needs. Housing is a key determinant of health, and poor housing conditions continue to cause preventable deaths and contribute to health inequalities\(^10\). An example in this area is the work carried out by Liverpool City Council in partnership with Liverpool Primary Care Trust – the “Healthy

---

\(^7\) Housing Act 2004

\(^9\) Choosing Health: Making healthy choices easier, Department of Health, 2004

\(^10\) The health impacts of poor private sector housing, LACORS, 2010
Homes Programme”. This has identified over 3,800 hazards and led to an estimated £4.8 million investment by landlords, delivering sustainable health improvements and enhancing community wellbeing.

2.2.3 Integrated care

It has been recognised by central government that to fully address the health needs of the population, services need to become more integrated and there needs to be better communication between different providers. Housing is a key aspect of this:

“Many people with mental and physical disabilities, complex needs, long-term conditions and terminal illness also need to access different health care, social care, housing and other services, such as education, and often simultaneously”11.

It is therefore essential that departments providing or regulating housing work with other council departments and health organisations to provide services that are integrated and take full account of the needs of the individual.

2.2.4 Public Health Outcomes Framework

The Public Health Outcomes Framework “Healthy lives, healthy people: Improving outcomes and supporting transparency”12 sets out desired outcomes for public health and how they will be measured. Many of the measurements have links to housing, some of the more relevant being:

- Falls and injuries in over 65’s
- Fuel poverty
- Excess winter deaths

2.2.5 Joint Strategic Needs Assessment (JSNA) and Joint Health and Wellbeing Strategies

The JSNA and joint health and wellbeing strategy allow health and wellbeing boards to analyse the health needs of their local population and to decide how to make best use of collective resources to achieve the priorities that are formed from these. The Department of Health document “Joint Strategic Needs Assessment and joint health and wellbeing strategies explained - Commissioning for populations” says “This will ensure better integration between public health and services such as housing and education that have considerable impact on the wider determinants of health”13.

2.2.6 Energy Act 2011

The Energy Act 2011 requires that from 2016 reasonable requests by tenants for energy efficiency improvements will not be able to be refused. Furthermore, from 2018 it will be unlawful for landlords to rent out properties that do not reach a minimum standard of energy efficiency (likely to be set at Energy Performance Certificate rating E14). While there will be various caveats to these powers, they will provide

14 https://www.gov.uk/getting-a-green-deal-information-for-householders-and-landlords
a new minimum standard for rented accommodation. Part of this current project for Kingston upon Thames includes provision of a private rented sector variable that should assist in identifying such dwellings.

2.2.7 Empty homes

Empty homes brought back into use will qualify for the New Homes Bonus where, for the following 6 years, the government will match fund the Council Tax on long term empty properties brought back into use. In addition, from 2012-15, £100million of capital funding from within the Affordable Homes Programme will be available to tackle problematic\textsuperscript{15} empty homes. Whilst the data provided by this project cannot necessarily assist with the actual identification of empty homes, the database provided would be the logical place for such information to be stored should it be gathered from other sources.

2.3 Other policy areas

The following policy areas, whilst not directly relating to environmental health services, will have an effect on demand and local authorities will need to be aware of the possible impact in their area.

2.3.1 Welfare Reform Act 2012

The key parts of this act for environmental health services are the sections relating to the under occupation of social housing, and the benefit cap. Whilst this will mainly affect tenants in the social rented sector it will undoubtedly have an impact on private sector services. Social tenants may find themselves being displaced into the private sector, increasing demand in this area, and the tenants of Registered Providers (RP’s) and some private landlords may have greater trouble affording rent payments. If tenants are in arrears on their rental payments then authorities may be met with reluctance from landlords when requiring improvements to properties.

2.3.2 Localism Act 2011

The Localism Act allows social housing providers to offer fixed term, rather than secure lifetime, tenancies. As with the Welfare Reform Act, this has a greater direct impact on the social rented sector, however, there is some concern this may lead to greater turnover of tenancies meaning such that some traditional social tenants may find themselves in the private rented sector.

Both of these policy changes above may increase the number of vulnerable persons in private sector properties. If this occurs any properties in this sector in poor condition are likely to have a far greater negative impact on the health of those occupiers

2.3.3 Potential increase in private rented sector properties

Policies such as the Build to Rent and the New Homes Bonus are aimed at increasing the supply of properties. As the private rented sector is already growing, it is reasonable to assume that many of the new properties being built will be rented to private tenants. Local authorities will need to be aware of the potential impact on the demand for their services and how their perception of their local area may have to change if large numbers of properties are built.

\textsuperscript{15} Properties that are likely to remain empty without direct financial support from government.
2.4 Local Authority Housing Statistics (LAHS)\textsuperscript{16} and EPC ratings

The purpose of these statistics is twofold – firstly to provide central government with data with which to inform and monitor government strategies, policies and objectives as well as contributing to national statistics on housing, secondly, to the local authorities themselves to help manage their housing stock. Local authorities are required to complete an annual return which covers a wide range of housing-related issues. Of particular relevance to this current project is “Section F: Condition of dwelling stock” which, amongst other things, requests the following information:

- Total number of dwellings and number of private sector dwellings with category 1 HHSRS hazards and the estimated costs of mitigating these
- Estimates of the number of HMOs and the number of mandatory licensable HMOs

Whilst the LAHS no longer requires reporting of average EPC ratings of the private sector stock and the proportion below a certain rating, this information remains pertinent due to the Energy Act 2011. Under this act new rules mean that from 2018 landlords must ensure that their properties meet a minimum energy efficiency standard, likely to be set at EPC band E\textsuperscript{17, 18}.

Results relating to LAHS statistics (category 1 hazards) and EPC ratings can be found in Section 4.2.

\textsuperscript{17} https://www.gov.uk/getting-a-green-deal-information-for-householders-and-landlords

\textsuperscript{18} Unless they have already installed the full range of measures possible under the Green Deal.
3 Overview of the BRE Dwelling Level Housing Stock Modelling Approach

3.1 Overview

This section provides a simplified overview of the BRE dwelling level housing stock modelling approach. More detail on the methodology is provided in Appendix B.

A stock modelling approach has been developed and used by BRE for many years and dwelling level models are used to estimate the likelihood of a particular dwelling meeting the criteria for each of the key indicators (and other outputs of interest). These outputs can then be mapped to provide the council with a geographical distribution of each of the key indicators which can then be used to target resources for improving the housing stock. The process itself is actually made up of a variety of data sources, calculations and models.

The models are principally informed by the Department for Communities and Local Government's (DCLG) English Housing Survey (EHS)\(^{19}\). The survey is not used to supply data for the database, but rather it allows the identification of patterns in the housing stock, so that this knowledge can be applied, in the form of mathematical algorithms, to impute key indicators and energy characteristics from other data available at the national level. The particular approach for Kingston upon Thames, however, makes significant use of the Experian UK Consumer Dynamics Database of dwelling and household indicators as inputs to the models. One example is the BRE SimpleCO\(_2\) Model which is based on dwelling level inputs from Experian and expands on these using imputation techniques to provide sufficient information to calculate the likely energy efficiency of each dwelling in the stock. Some of the key housing indicators, such as HHSRS excess cold category 1 hazards and BRE’s SimpleSAP\(^{20}\), can be directly inferred from this data.

Figure 1 shows a simplified flow diagram of the overall BRE housing stock modelling approach. The process is made up of a series of data sources and models which, combined with various imputation and regression techniques and the application of other formulae, make up the final database. The database is essentially the main output of the modelling and provides information on the key indicators and other data requirements (e.g. energy efficiency variables). More detailed information on the data sources and models is provided in Appendix B, but to summarise:

**The data sources are:**
EHS, Experian, Ordnance Survey (OS) MasterMap

**The Models are:**
SimpleSAP, Fuel Poverty, HHSRS (all hazards, falls hazards and excess cold), Disrepair and Low Income Households

---

\(^{19}\) The most recent survey used in the housing stock models is 2011.

\(^{20}\) A Simplified version of the SAP model that produces an output broadly comparable to SAP. The SimpleSAP model is distinct from both full SAP and RD SAP in that uses a smaller, simplified set of inputs.
The data sources and models are linked as shown in the flow diagram and the modelling process itself can be divided into “energy inputs” and “other inputs”, which are summarised as follows:

**Energy inputs** - are developed from Experian. The EHS data is used to impute (using cold deck imputation\(^{21}\)) and interpolate where there are gaps in the data. The “energy inputs” are then fed into the SimpleCO\(_2\) Model to produce the “energy outputs” for the database plus information on excess cold for the HHSRS Model and information on energy costs for the Fuel Poverty Model.

**Other inputs** – are developed from Experian, OS MasterMap and other local data sources. The EHS data is used to impute (using cold deck imputation\(^{21}\)) and interpolate where there are gaps in the data. The “other inputs” are then fed into the HHSRS, Disrepair, and Low Income Models (note that tenure data is fed directly into the database). Information from the EHS also feeds into the Fuel Poverty, HHSRS, Disrepair and Low Income Models.

---

\(^{21}\) Cold deck imputation is a process of assigning values in accordance with their known proportions in the stock.
Figure 1: Simplified flow diagram of overall BRE housing stock modelling approach (N.B. the EHS data is only used to inform the mathematical algorithms of the model – it does not provide data)
3.2 Breakdown of the housing stock by tenure - validation

Providing the results split by tenure is useful since it can have an effect on how resources and improvement policies are targeted. This report is particularly focussed on private sector stock which is made up of owner occupied and private rented dwellings. The remainder of the housing stock consists of social housing.

The total number of dwellings in Kingston upon Thames from the BRE database uses the tenure split derived from the purchased Experian tenure variable.

Since it is possible for private rented dwellings to become owner occupied and vice versa relatively easily, it is difficult to accurately predict the actual tenure split at any given point in time. A validation process was undertaken to compare the tenure split from the database to the 2011 Census figures\(^{22}\). The results of the validation exercise show that the differences between the tenure split from the database compared to the Census figures are relatively small (see Figure 2), suggesting that the database should provide a good overview of the housing stock in Kingston upon Thames. Furthermore, Map 1 and Map 2 show that the geographical distributions look very similar, again giving confidence that the database provides a good overview of Kingston upon Thames’ housing stock.

**Figure 2**: Tenure split – comparison of BRE Housing Stock Database outputs with 2011 Census figures for Kingston upon Thames

Map 1: Distribution of estimated percentage of private rented dwellings in Kingston upon Thames – based on database
Map 2: Distribution of estimated percentage of private rented dwellings in Kingston upon Thames – based on 2011 Census Data (Neighbourhood Statistics)
4 Results from the BRE Dwelling Level Housing Stock Models and Database

As described in the previous section, the housing stock modelling process consists of a series of different stock models with the main output being the database. The results in this section have been obtained from interrogating the database at the level of the local authority as a whole to give a useful overview for Kingston upon Thames. Information at ward level, however, is provided in the maps, in Section 4.2.4 and can also be obtained from the database which has been supplied as part of this project (see Appendix C for instructions).

The first sub-section below provides a map of the wards in Kingston upon Thames. The results are then displayed in the following sub-sections:

- Key indicators:
  - Kingston upon Thames compared to England
  - Key indicators by tenure for Kingston upon Thames
  - Key indicators mapped by COA for Kingston upon Thames private sector stock
  - Ward level results for the key indicators

- Information relating to LAHS reporting and EPC ratings:
  - Category 1 hazards
  - EPC ratings

4.1 Overview of Kingston upon Thames

Map 3 below shows the 16 wards in Kingston upon Thames. The data in the report is separated into wards and then further divided into Census Output Areas (COA's).
Map 3: The wards in Kingston upon Thames
4.2 Key indicators

4.2.1 Kingston upon Thames compared to England

Table 2 and Figure 3 show the results for each of the key indicators in Kingston upon Thames compared to England (EHS 2011) and split into all stock and private sector stock. Figure 4 shows the results of the SimpleSAP ratings.

For all stock, Kingston upon Thames performs better than the EHS average for all the indicators; in particular all hazards (7% compared to 15%), fuel poverty 10% definition (9% compared to 15%) and low income households (22% compared to 33%).

For the private sector stock, Kingston upon Thames again performs better than the EHS average for all the indicators; in particular HHSRS all hazards (7% compared to 17%), fuel poverty 10% definition (9% compared to 15%) and low income households (16% compared to 24%).

The average SimpleSAP ratings in Kingston upon Thames (Figure 4) are lower than those for the England average for both all stock and for the private sector stock. It is not unusual for urban areas to perform better than the country as a whole due to a greater number of flats, which are more energy efficient due to reduced heat loss areas, and due to the greater likelihood of being on gas, a more efficient heating fuel.

**Figure 4:** Average SimpleSAP ratings for all stock and private sector stock – Kingston upon Thames compared to England (EHS 2011)
4.2.2 Key indicators by tenure – Kingston upon Thames

The private sector stock can be further split by tenure – owner occupied and private rented - with the difference between total private sector stock and total housing stock being the social housing stock. Table 3 and Figure 5 below show the results for each of the key indicators split by tenure and Figure 6 shows the SimpleSAP ratings by tenure.

The social stock is generally better than the private sector stock particularly for the indicators relating to falls, fuel poverty and energy efficiency (SimpleSAP). Social stock tends to be more thermally efficient than the private stock partly due to the prevalence of flats, and partly due to being better insulated owing to the requirements placed on social housing providers, for example through the Decent Homes Programme. As would be expected, the social stock is generally worse than the private sector stock for the low income households indicator.

The social data should be treated with some caution as the social rented stock, particularly when largely comprising stock owned by a single landlord, is more difficult to model than the private sector. This is because the decisions of an individual property owner usually only affect a single dwelling out of the thousands of private sector stock whereas the policies and decisions of a single landlord can have a very great effect on a large proportion of the social stock. The social rented results are therefore best considered as a benchmark which takes account of the age, type, size and tenure against which the landlord’s own data could be compared.

Focussing on the tenures within the private sector stock, the private rented stock is generally worse than the owner occupied stock with the exception of energy efficiency (SimpleSAP). The private rented stock is considerably worse than the owner occupied stock for the indicators of low income households and fuel poverty.

4.2.3 Key indicators mapped by Census Output Area (COA) – Kingston upon Thames private sector stock

Some of the key indicators are also provided in map form below along with a brief description of each indicator\(^{23}\), thus enabling quick observation of the geographical distribution of properties of interest. The maps show the percentages of private sector dwellings in each Census Output Area (COA) that are estimated to have each of the key indicators.

The ranges shown in the map keys are defined based on the Jenks’ Natural Breaks algorithm of the COA statistics\(^{24}\). The outputs in the lightest and darkest colours on the maps show the extreme ends of the range, highlighting the best and the worst areas.

Maps at COA level are provided for the following key indicators in Map 4 to Map 10 below:

- The presence of a category 1 HHSRS hazard
- The presence of a category 1 hazard for excess cold
- Levels of fuel poverty
- Dwellings occupied by low income households
- Dwellings with a category 1 excess cold hazard that are occupied by a low income household
- The average SimpleSAP\(^{25}\) rating

These maps are extremely useful in showing the geographical distribution for single key indicators. Maps can also be produced for a combination of indicators, such as dwellings with an excess cold hazard which are also occupied by low income households, as shown in Map 9.

The maps also highlight the differences between areas, showing that the results for some areas are much worse than for others and these are the specific areas which might warrant attention. The maps also show that even within wards there can be large differences between the results at COA level.

4.2.3.1 HHSRS

The Housing Health and Safety Rating System (HHSRS) is a risk-based evaluation tool to help local authorities identify and protect against potential risks and hazards to health and safety from any deficiencies identified in dwellings. It was introduced under the Housing Act 2004\(^{7}\) and applies to residential properties in England and Wales.

The HHSRS assesses 29 categories of housing hazard. Each hazard has a weighting which will help determine whether the property is rated as being category 1 (serious) or category 2 (other)\(^{26}\).

The HHSRS map (Map 4) shows that there are pockets of high levels of hazards throughout the local authority, with concentrations of higher levels of hazards in St Mark's, Berrylands and Beverley wards. It

\(^{23}\) See Appendix A for full definitions.

\(^{24}\) Natural breaks classes are based on natural groupings inherent in the data.

\(^{25}\) Important note: Whilst it is possible to provide “SimpleSAP” ratings from the “SimpleCO2” software, under no circumstances must these be referred to as “SAP” as the input data is insufficient to produce an estimate of SAP or even RdSAP for an individual dwelling that meets the standards required by these methodologies.

\(^{26}\) Housing Health and Safety Rating System Operating Guidance, ODPM, 2006
is reasonable to expect that areas with greater numbers of older properties tend to record higher levels of excess cold and falls hazards.

There are relatively low levels of excess cold hazards in Kingston upon Thames, so when looking at concentrations of excess cold, this is only relative to Kingston upon Thames as a whole. There are again pockets of high levels of hazards throughout the local authority, with concentrations of higher levels of hazards in St Mark's, Berrylands and Beverley—see Map 5.
Map 4: Percentage of private sector dwellings in Kingston upon Thames with the presence of a HHSRS category 1 hazard
Map 5: Percentage of private sector dwellings in Kingston upon Thames with the presence of a HHSRS category 1 hazard for excess cold
4.2.3.2 Fuel poverty

This report covers both the original definition and the new definition of fuel poverty which is currently being rolled out by government.

The original definition states that a household is said to be in fuel poverty if it spends more than 10% of its income on fuel to maintain an adequate level of warmth (defined as 21°C for the main living area, and 18°C for other occupied rooms in the 2012 Hills Fuel Poverty Review)\(^{27}\). For the purposes of this report this is termed “fuel poverty (10%)”.

Under the new definition, a household is said to be in fuel poverty if they have required fuel costs that are above average (the national median level) and were they to spend that amount they would be left with a residual income below the official poverty line. For the purposes of this report this is termed “fuel poverty (Low Income High Costs)”.

**Map 6** shows that, based on the fuel poverty 10% definition, the higher concentrations are in the St James, Berrylands and Beverley wards, though there are pockets of high concentrations across the local authority.

For comparison, **Map 7** shows the results based on the fuel poverty Low Income High Costs definition, whilst again there are pockets of high concentration throughout the local authority the wards with the highest concentrations overall are Norbiton, Beverley and St James.

4.2.3.3 Low income households

A low income household is defined as a household in receipt of:

- Income support
- Housing benefit
- Attendance allowance
- Disability living allowance
- Industrial injuries disablement benefit
- War disablement pension
- Pension credit
- Child tax credit
- Working credit

For child tax credit and working tax credit, the household is only considered a low income household if it has a relevant income of less than £15,050.

The definition also includes households in receipt of Council Tax benefit and income based Job Seekers Allowance.

Compared to the national figures Kingston upon Thames has lower levels of low income households. Map 8 shows that Norbiton stands out as having higher concentrations of low income households.

Map 9 provides an additional layer of information, with the data for low income households being combined with HHSRS excess cold data. This provides a vital picture of where vulnerable people are likely to be living in poor housing. The map indicates that Berrylands and St. Mark’s appear to have higher levels of vulnerable people living in properties suffering from excess cold.
Map 8: Percentage of private sector dwellings in Kingston upon Thames occupied by low income households
Map 9: Percentage of private sector dwellings in Kingston upon Thames with both the presence of a HHSRS category 1 hazard for excess cold and occupied by low income households.
4.2.3.4 SimpleSAP

The average SimpleSAP map (Map 10) shows a mix of SimpleSAP ratings across the authority with areas such as Alexandra, St James and Coombe Vale having lower average SimpleSAP ratings. Areas such as these, which haven't shown up as being particularly poor for the other key indicators, can be due to that area having larger, older homes where little work has been done by the occupiers to improve energy performance. The size of the home itself is not a factor in SimpleSAP, but these homes are more likely to be semi-detached or detached, and therefore have larger heat loss areas.
Map 10: Average SimpleSAP ratings per dwelling in Kingston upon Thames private sector stock
4.2.4 Ward level results for the key indicators – total stock and private sector stock

The previous maps have provided a visual representation of the key indicators at Census Output Area (COA) level. The following tables provide the complete set of figures at ward level for the key indicators; firstly, for the total stock (Table 4) and secondly, for the private sector stock (Table 5). This allows a direct comparison between the wards in Kingston upon Thames.

4.3.2 EPC ratings in the Kingston upon Thames private sector stock

Figure 7 below shows the bands A – G and corresponding SAP ratings in brackets. The columns show the number and percentage of Kingston upon Thames’ private sector stock falling into each of the EPC ratings bands.

The estimated average SimpleSAP for the private sector stock in Kingston upon Thames is 54 which corresponds to an EPC rating of E. The number of private sector dwellings with an EPC rating below band E is estimated to be 5,284 (9.5%).

Under the Energy Act 2011, new rules mean that from 2018 landlords must ensure that their properties meet a minimum energy efficiency standard, likely to be set at EPC band E.29, 30

28 Note that these costs are estimated based on standardised cost assumptions intended for comparison purposes. If available, local data on costs – such as grant or loan aided works – could be used; however, this type of data is usually biased. The estimates here are therefore considered as a useful starting point.

29 https://www.gov.uk/getting-a-green-deal-information-for-householders-and-landlords
Figure 8 below shows the breakdown of SimpleSAP results into the A – G bands for the private rented stock only. The number of private rented dwellings in Kingston upon Thames with a rating below band E (i.e. bands F and G), is estimated to be 1,505 (10.4%).

30 Unless they have already installed the full range of measures possible under the Green Deal.
5 Conclusion and recommendations

5.1 Conclusion

The Royal Borough of Kingston upon Thames commissioned BRE to undertake a series of modelling exercises on their housing stock. This report describes the modelling work and provides details of the results obtained from the dwelling level model and database. The database is also provided to the council to enable them to obtain specific information whenever required.

The stock models and database provide the council with dwelling level information, focusing on private sector housing, for the following:

- The percentage of dwellings meeting each of the key indicators for Kingston upon Thames overall and broken down by tenure and then mapped by COA (private sector stock only)
- Information relating to LAHS reporting for the private sector stock - category 1 hazards, as well as information on EPC ratings

Such information will facilitate the decision making process for targeting resources to improve the condition of housing and to prevent ill health resulting from poor housing conditions. Furthermore, the results of this project provide Kingston upon Thames with information which will assist in housing policy and strategy development whether these are inspired locally, arise from obligations under the Housing Act 2004 or as responses to government initiatives such as DCLG’s Housing Strategy Policy, Green Deal and ECO.

5.2 Recommendations

The current database could be enhanced to include the addition of various other sources of data (if they are available to the council). If such data were available BRE are able31 to integrate these local data sources into the current database.

Examples of such data are:

- **Energy Performance Certificate (EPC) data**
  
  EPCs contain data on key dwelling energy characteristics (e.g. energy demand, excess cold, SimpleSAP) and where these are available they can be used in preference to the modelled data (it should be noted that to comply with bulk EPC data licencing requirements the EPC data is only used to inform the energy efficiency aspects of the model).

- **Local Land and Property Gazetteer (LLPG) data**
  
  The Unique Property Reference Number (UPRN) from the LLPG can be used to uniquely identify all properties, while the address details from the LLPG can be used to merge the BRE models and EPC data using address matching.

---

31 Dependent on a successful feasibility assessment of the data.
- **Households on benefits**

Data regarding any households in receipt of either Council Tax Support or Housing Allowance could be used to enhance the low income model, making the targeting of individual low income households more accurate.

- **Local repair schemes**

Data from any local repair schemes, including the use of repair grants, could be used to enhance the Disrepair Model.

- **Local energy improvement schemes**

Any local schemes to improve the energy efficiency of dwellings, including national schemes for which local data has been made available to Kingston upon Thames, could be used to further enhance the energy models (SimpleSAP, excess cold, fuel poverty).

Furthermore, Kingston upon Thames has also commissioned BRE to carry out an analysis of the condition of the housing stock and its health impact, through a Health Impact Assessment. The results of this are provided in a separate report which also provides a cost benefit analysis of mitigating Housing Health and Safety hazards within the stock and a bespoke analysis of various vulnerable groups against fuel poverty figures at LSOA level.

Further assistance can be provided in the form of a Healthy Homes Advisory Service. This involves assisting the local authority in using the data from stock modelling and the health impact assessment to proactively assist vulnerable residents living in the poorest quality housing in the local authority area. The toolkit will allow Kingston upon Thames to target the poorest quality housing and maximise the joint working opportunities with health and community groups in the area.
Appendix A  Definitions of the key indicators

1. House condition indicators
   a. The presence of a category 1 hazard under the Housing Health and Safety Rating System (HHSRS) – reflecting both condition and thermal efficiency
      Homes posing a category 1 hazard under the HHSRS – the system includes 29 hazards in the home categorised into category 1 (serious) or category 2 (other) based on a weighted evaluation tool. Note that this includes the hazard of excess cold which is also included as one of the energy efficiency indicators.

      The 29 hazards are:

      | Hazard                                                      | Code  |
      |--------------------------------------------------------------|-------|
      | 1 Damp and mould growth                                     | 16    |
      | 2 Excess cold                                               | 17    |
      | 3 Excess heat                                               | 18    |
      | 4 Asbestos                                                  | 19    |
      | 5 Biocides                                                  | 20    |
      | 6 Carbon Monoxide and fuel combustion products              | 21    |
      | 7 Lead                                                      | 22    |
      | 8 Radiation                                                 | 23    |
      | 9 Uncombusted fuel gas                                      | 24    |
      | 10 Volatile Organic Compounds                               | 25    |
      | 11 Crowding and space                                       | 26    |
      | 12 Entry by intruders                                       | 27    |
      | 13 Lighting                                                 | 28    |
      | 14 Noise                                                    | 29    |
      | 15 Domestic hygiene, Pests and Refuse                       |       |
      | 16 Food safety                                              |       |
      | 17 Personal hygiene, Sanitation and Drainage                |       |
      | 18 Water supply                                             |       |
      | 19 Falls associated with baths etc.                         |       |
      | 20 Falling on level surfaces etc.                           |       |
      | 21 Falling on stairs etc.                                   |       |
      | 22 Falling between levels                                   |       |
      | 23 Electrical hazards                                       |       |
      | 24 Fire                                                     |       |
      | 25 Flames, hot surfaces etc.                                |       |
      | 26 Collision and entrapment                                 |       |
      | 27 Explosions                                               |       |
      | 28 Position and operability of amenities etc.               |       |
      | 29 Structural collapse and falling elements                 |       |

   b. The presence of a category 1 hazard for falls (includes “falls associated with baths”, “falling on the level” and “falling on stairs”)
      The HHSRS Falls Model includes the 3 different falls hazards where the vulnerable person is over 60 as listed above.

   c. Dwellings in disrepair (based on the former Decent Homes Standard criteria for Disrepair)
      The previous Decent Homes Standard states that a dwelling fails this criterion if it is not found to be in a reasonable state of repair. This is assessed by looking at the age of the dwelling and the condition of a range of building components including walls, roofs, windows, doors, electrics and heating systems).

2. Energy efficiency indicators:
   a. The presence of a category 1 hazard for excess cold (using SAP ratings as a proxy measure in the same manner as the English House Condition Survey)
      This hazard looks at households where there is a threat to health arising from sub-optimal indoor temperatures. The HHSRS assessment is based on the most low income group for this hazard – persons aged 65 years or over (note that the assessment requires the hazard to
be present and potentially affect a person in the low income age group should they occupy that dwelling. The assessment does not take account of the age of the person actually occupying that dwelling at that particular point in time).

The English Housing Survey (EHS) does not measure the actual temperatures achieved in each dwelling and therefore the presence of this hazard is measured by using the SAP rating as a proxy. Dwellings with a SAP rating of less than 31.5 (SAP 2005 methodology) are considered to be suffering from a category 1 excess cold hazard.

b. An estimate of the SAP rating which, to emphasise its origin from a reduced set of input variables, is referred to as “SimpleSAP”

The Standard Assessment Procedure (SAP) is the UK Government’s standard methodology for home energy cost ratings. SAP ratings allow comparisons of energy efficiency to be made, and can show the likely improvements to a dwelling in terms of energy use. The Building Regulations require a SAP assessment to be carried out for all new dwellings and conversions. Local authorities, housing associations, and other landlords also use SAP ratings to estimate the energy efficiency of existing housing. The version on which the Average SAP rating model is based is SAP 2005.

The SAP ratings give a measure of the annual unit energy cost of space and water heating for the dwelling under a standard regime, assuming specific heating patterns and room temperatures. The fuel prices used are averaged over the previous 3 years across all regions in the UK. The SAP takes into account a range of factors that contribute to energy efficiency, which include:

- Thermal insulation of the building fabric
- The shape and exposed surfaces of the dwelling
- Efficiency and control of the heating system
- The fuel used for space and water heating
- Ventilation and solar gain characteristics of the dwelling

3. Household vulnerability indicators:

a. Fuel poverty - 10% definition

This definition states that a household is said to be in fuel poverty if it spends more than 10% of its income on fuel to maintain an adequate level of warmth (usually defined as 21°C for the main living area, and 18°C for other occupied rooms). This broad definition of fuel costs also includes modelled spending on water heating, lights, appliances and cooking.

The fuel poverty ratio is defined as:

\[
\text{Fuel poverty ratio} = \frac{\text{Fuel costs} \times \text{price}}{\text{Full income}}
\]

If this ratio is greater than 0.1 then the household is in fuel poverty.

The definition of full income is the official headline figure and in addition to the basic income measure, it includes income related directly to housing (i.e. Housing Benefit, Income Support for Mortgage Interest (ISMI), Mortgage Payment Protection Insurance (MPPI), Council Tax Benefit (CTB)).
Fuel costs are modelled, rather than based on actual spending. They are calculated by combining the fuel requirements of the household with the corresponding fuel prices. The key goal in the modelling is to ensure that the household achieves the adequate level of warmth set out in the definition of fuel poverty whilst also meeting their other domestic fuel requirements.

b. Fuel poverty - Low Income High Costs definition
The government has recently set out a new definition of fuel poverty which it intends to adopt under the Low Income High Costs (LIHC) framework. Under the new definition, a household is said to be in fuel poverty if:

- They have required fuel costs that are above average (the national median level)
- Were they to spend that amount they would be left with a residual income below the official poverty line

c. Dwellings occupied by a low income household
A household in receipt of:

- Income support
- Housing benefit
- Attendance allowance
- Disability living allowance
- Industrial injuries disablement benefit
- War disablement pension
- Pension credit
- Child tax credit
- Working credit

For child tax credit and working tax credit, the household is only considered a low income household if it has a relevant income of less than £15,050.

The definition also includes households in receipt of Council Tax benefit and income based Job Seekers Allowance.

---

This Appendix provides a more detailed description of the models which make up the overall housing stock modelling approach and feed into the database. The process is made up of a series of data sources and Models which, combined with various imputation and regression techniques and the application of other formulae, make up the final database. The database is essentially the main output of the modelling and provides information on the key indicators and other data requirements (e.g. energy efficiency variables). An overview of the approach and a simplified flow diagram are provided in Section 3 of this report.

The models making up the overall housing stock modelling approach are:

- SimpleCO₂ Model
- Fuel Poverty Model
- HHSRS (all hazards, falls hazards and excess cold) Models
- Disrepair Model
- Low Income Households Model

**Figure B.1** shows the data flows for the stock modelling approach, showing which models each of the outputs in the database (split into the key indicators and other information) come from. The exception is the Green Deal variables (if used) which come directly from the energy inputs, and the tenure and HMO data (if used) which come directly from the other inputs.

Section B.1 describes the SimpleCO₂ Model in more detail, Section B.2 provides more information on the other four models and Section B.3 gives details of the OS MasterMap/geomodelling approach.
**Figure B.1: Simplified data flow for the housing stock modelling approach**

B.1 BRE SimpleCO₂ Model

BRE have developed a variant of the BREDEM³³ software, named “SimpleCO₂”, that can calculate outputs from a reduced set of input variables. These outputs are indicative of the full BREDEM outputs and the minimum set of variables the software accepts is information on:

- Dwelling type
- Dwelling age
- Number of bedrooms
- Heating fuel
- Heating system
- Tenure

The Experian UK Consumer Dynamics Database is used as a source of these variables and they are converted into a suitable format for the SimpleCO₂ software. However, these variables alone are insufficient for the software to calculate the “SimpleSAP” rating or carbon emissions estimate (one of the outputs of the SimpleCO₂ Model). Additional variables are required and as these values cannot be precisely inferred then a technique known as cold deck imputation is undertaken. This is a process of assigning values in accordance with their known proportions in the stock. For example, this technique is used for predicting heating fuels as the Experian data only confirms whether a dwelling is on the gas network or not. Fuel used by dwellings not on the gas network is unknown, so in most cases this information will be assigned using probabilistic methods. The process is actually far more complex e.g. dwellings with particular characteristics such as larger dwellings are more likely to be assigned with oil as a fuel than smaller dwellings.

The reason for taking this approach is to ensure that the national proportions in the data source are the same as those found in the stock nationally (as predicted by the EHS or other national survey). Whilst there is the possibility that some values assigned will be incorrect for a particular dwelling (as part of the assignment process has to be random) they ensure that examples of some of the more unusual types of dwelling that will be present in the stock are included.

Whilst this approach is an entirely sensible and commonly adopted approach to dealing with missing data in databases intended for strategic use, it raises issues where one of the intended uses is planning implementation measures. It must therefore be kept in mind at all times that the data provided represents the most likely status of the dwelling, but that the actual status may be quite different. That said, where EPC data has been used, the energy models (which use EPC data) are likely to be more accurate.

It is important to note that some variables have been entirely assigned using cold decking imputation techniques. These include presence of cavity wall insulation and thickness of loft insulation as there is no reliable database with national coverage for these variables.

---

³³ Building Research Establishment Domestic Energy Model, BRE are the original developers of this model which calculates the energy costs of a dwelling based on measures of building characteristics (assuming a standard heating and living regime). The model has a number of outputs including an estimate of the SAP rating and carbon emissions.
The “SimpleCO2” software takes the combination of Experian and imputed data and calculates the
“SimpleSAP” rating for each dwelling in the national database. The calculated “SimpleSAP” ratings are
the basis of the estimates of SAP and excess cold. How the other key variables are derived is discussed
later in this Appendix.

Because the estimates of “SimpleSAP” etc. are calculated from modelled data it is not possible to
guarantee the figures. They do, however, provide the best estimates that we are aware can be achieved
from a data source with national coverage and ready availability. The input data could, however, be
improved in its:

- accuracy for example through correcting erroneous values,
- depth of coverage, for example by providing more detailed information on age of dwellings,
- breadth by providing additional input variables such as insulation.

Improving any of these would enhance the accuracy of the output variables and for this reason it is
always worth considering utilising additional information sources where they are available. Using EPC
data will go some way towards meeting these improvements by providing more accurate data.

B.2 Housing Condition and Low Income Household Models

This section provides further information on the remaining four models – fuel poverty, HHSRS, disrepair
and low income households. These models are discussed together since the approach used for each one
is broadly the same.

These models are not based solely on the thermal characteristics of the dwelling, and in some cases are
not based on these characteristics at all. A top down methodology has been employed for these models,
using data from the EHS and statistical techniques, such as logistic regression, to determine the
combination of variables which are most strongly associated with failure of each standard. Formulae have
been developed by BRE to predict the likelihood of failure based on certain inputs. The formulae are then
applied to the variables in the national Experian dataset to provide a likelihood of failure for each dwelling.
Each individual case is then assigned a failure/compliance indicator based on its likelihood of failure and
on the expected number of dwellings that will fail the standard within a given geographic area. Thus if the
aggregate values for a census output area are that 60% of the dwellings in the area fail a particular
standard then 60% of the dwellings with the highest failure probabilities will be assigned as failures and
the remaining 40% as passes.

The presence of a category 1 hazard failure is the only exception to this as it is found by combining
excess cold, fall hazards and other hazards such that failure of any one of these hazards leads to failure
of the standard.

B.3 OS MasterMap information

The OS data has been used to update a number of the SimpleCO2 model inputs. The most valuable use
of the OS data is the ability to determine the dwelling type with much greater confidence.

The existing dwelling type is replaced with a new dwelling type derived from OS data. By looking at the
number of residential address points it can be inferred whether the building is a house or block of flats
(houses have one residential address point and blocks of flats have two or more).

Houses - where the dwelling is a house the number of other buildings it is attached to can be observed
and the following assumptions made:

- If there are no other dwellings attached, the house is detached.
If two dwellings are joined to one another, but not to any other dwellings, they are semi-detached.

If they are attached to two or more other dwellings, they are mid terraced.

If they are attached to only one dwelling, but that dwelling is a mid-terrace, they are an end-terrace.

**Flats** - if the building is a block of flats, its exact nature is determined by its age and the number of flats in the block and the following assumptions made:

- If there are between two and four flats in the block (inclusive) and the dwelling was built before 1980 then it is a conversion.
- Otherwise it is purpose built.

This information can also be used to reconcile discrepancies within blocks of flats, terraced and semi-detached houses. These discrepancies occur in variables such as dwelling age, location of flat in block, number of storeys, loft insulation, wall insulation, wall type and floor area.

Looking at dwelling age, although the OS data does not itself provide any information on age, it does allow reconciliation of age data within semi-detached, terraces and blocks of flats.

Where a group of buildings are all attached in some way, such as a terrace, it is logical to assume that they were built at the same time. Therefore the age of each building is replaced with the most common age among those present. Where the most common age occurs in equal numbers, this is resolved by looking at the average age of houses in the same postcode.

If one dwelling has an age that is notably newer than its neighbours, then the age is not changed, as it is assumed that the original dwelling was destroyed and rebuilt.
Figure B. 2 and Figure B. 3 below show how the initial base data is adjusted using the OS data to produce more consistent and reliable results.

Considering the number of storeys and the location of a flat in its block, if the OS data reveals that the dwelling type is significantly different from the original value – specifically if a house becomes a flat, or vice versa then the variables are adjusted. If this is the case a new location for the flat within the block or the number of storeys will be imputed using the same method as before, but taking into account the revised dwelling type.

Similarly with floor area, loft insulation and wall type - if the dwelling type or location of a flat within a block changes as a result of OS data then the variables are calculated using the same method of imputation as the original models, but taking into account the new data.
Figure B. 2: Dwelling level map showing the base data, prior to using the OS data

Figure B. 3: Dwelling level map showing the OS updated data
The BRE Dwelling Level Housing Stock Database is the final output of the overall stock modelling approach described in Section 3 and Appendix B. The database has been designed to provide local authorities with a number of different options for summarising or investigating their data and generating lists of properties of interest. This Appendix provides details of how to use the database.

C.1 Overview

The database will automatically open on the interface screen as shown in Figure C.1 below.

**Figure C.1:** BRE dwelling level housing stock database – opening interface screen
On the left hand side of the database is a vertical column known as the “navigational pane”. Under the heading “BRE HSM Base Data” there are 7 tables which hold the BRE housing stock model data. The tables are as follows:

**Table C.1: Summary of information provided in each table in the database**

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 Address Information</td>
<td>Address details (building names, house numbers, postcodes), COA and Ward for each address</td>
</tr>
<tr>
<td>1 HSM Base Data Dwelling Level</td>
<td>Dwelling level housing stock model data and Experian tenure variable. SimpleSAP results: score out of 100</td>
</tr>
<tr>
<td></td>
<td>All other indicators: 0 = pass the standard, 1 = fail</td>
</tr>
<tr>
<td>2 HSM Base Data Postcode Level</td>
<td>Summary information and statistics for each of the aggregated levels specified.</td>

</tr>
<tr>
<td>4 HSM Base Data Ward Level</td>
<td></td>
</tr>
<tr>
<td>5 HSM Base Data LA Level</td>
<td></td>
</tr>
</tbody>
</table>

**C.2 Using the database**

The rest of the screen is the main interface which has been developed with a number of standard queries that will present the user with information likely to be of use when reviewing data in order to design a housing stock strategy. There are 3 main sections to the interface: “Summary data”, “Search for street or postcode” and “Filter by criteria”. These sections are described in more detail below.

**C2.1 “Summary data”**

These options allow the user to generate summaries of their data at different levels of aggregation. The three different levels of aggregation are:

- Local authority
- Ward
- LSOA
- COA

**Notes:**

34 An additional table showing the results at LSOA level has been provided for Kingston upon Thames to enable comparison with their health data included in the HIA bespoke analysis.

35 If the Experian tenure variable has been purchased.
There are two types of summaries available at each level - totals and percentages:

- Totals give the user the total number of dwellings that fail a particular standard, for example, the total number of dwellings that have a HHSRS category 1 hazard in the authority.
- Percentages tell the user the percentage of dwellings that fail a criterion, for example, the percentage of dwellings suffering from HHSRS category 1 excess cold hazards.

C2.2 “Search for streets or postcodes”

These options allow the user to search for particular areas, either by street name or postcode. By clicking on a search button the user will be asked to type in either a street or postcode. A table will then be shown which provides a list of all dwellings in the street or postcode requested.

If the full name of the street is not known, wildcard characters can be used to search for close matches. A wildcard character is one that can stand in for any other letter or group of letters. Access uses an asterisk (*) as the wildcard character. For example entering “Abbey*” will return any street name starting with “Abbey”, for example, “Abbey Road”, “Abbey Close”, “Abbeyfield” etc. Wildcard characters can be used at both the beginning and the end of the search text. For example, by entering “*Abbey*” would find “Abbey Road”, “Old Abbey Road” etc.

The street names used are those provided in the Local Land and Property Gazetteer. It can sometimes be the case that a street name can be written differently across databases (e.g. “Rose Wood Close” or “Rosewood Close”). If a road name does not appear to be present, try using wildcard characters to check for alternatives.

The postcode search facility works in a similar manner. Entering “BN15 0AD” will find all dwellings in that exact post code, but entering “BN15*” will find all dwellings whose postcode begins with BN15.

**Note:** always close the results of an existing search before starting a new one. Clicking the button when the results of an existing search are still open will simply return to the results of that search. A search, or any other table, can be closed by clicking the “x” in the top right corner of the table window.
C2.3 “Filter by criteria”

This section allows the user to select dwellings based on one or more criteria / key indicators of interest.

First, the user needs to select which tenure(s) they are interested in by using the “Select stock to view” on the right hand side of the box.

The default setting is that no tenures are selected, so the user will need to select at least one in order to get any results. Multiple tenures can be selected, so for the results for all the private stock select both owner occupied and private rented.

Once one or more of the tenures has been selected, choose one or more of the indicators of interest either by selecting an indicator e.g. HHSRS cat.1 hazards will return dwelling with fail HHSRS, or for SimpleSAP enter a rating to select dwellings on and below the rating.

Once a tenure(s) and indicator(s) have been selected clicking the ‘Filter by criteria’ button will return the addresses matching the chosen criteria.

As with the searches, close the results of an existing selection before starting a new one.

C.3 Creating Excel files

Whilst it is possible to copy the data from any of the queries accessed from the interface screen, an option has been added to make this process easier. To output results to Excel click the “Write to Excel” check box at the bottom right of the screen. As long as this box is checked, clicking any of the summary data, search or criteria selection buttons will cause the resulting data to be written to Excel instead of being displayed.

If this option is selected when any button is clicked the database requests a format for the output data. Once the appropriate file format is selected, click “OK” and choose a file name and location and click “OK” to save the file.

This function means it is possible to rapidly export summary tables for inclusion in reports, or lists of dwellings which can be used to target improvement programmes.

36 If the Experian tenure variable has not been purchased this section is locked and only private sector stock is shown.
